

## Security management

Fortinet has unveiled the FortiManager-3000 System, a tool for centrally configuring, managing and monitoring large-scale security deployments.

FortiManager-3000 extends the capabilities of Fortinet's management platform to enable large enterprises, service providers and telecommunications carriers to efficiently manage up to 5000 FortiGate antivirus firewall systems, regardless of geography. The system improves network security and maximises IT resources by ensuring consistent definition and application of security policies across some or all FortiGate systems on a network, and provides a central point for monitoring system status and logging traffic and threat activity. The system features: comprehensive element management; automated policy management; granular, role-based administration; device grouping; and centralised logging facilities.

All FortiGate systems come with FortiOS 2.8, firmware that offers features such as spyware and antivirus protections combined with IDP and stateful firewall capabilities to deliver Fortinet's Dynamic Threat Prevention. FortiOS 2.8 also includes antivirus heuristic support to help prevent widespread zero-day attacks for previously unknown viruses, anti-span capabilities and web content filtering through Fortinet's FortiGuard service.
